TRAFFIC COUNT DATABASE

## 1 INTRODUCTION

### 1.1 BACKGROUND

1.1.1. Selby is a local government district of North Yorkshire. Selby District Council (SDC) is the local authority for a number of wards within Selby district, including Selby East, Selby West, Tadcaster, Sherburn in Elmet and Eggborough. It is the southernmost district of North Yorkshire, bound by the unitary authority of City of York to its north, East Riding of Yorkshire to its east, Wakefield council to its south and City of Leeds to its west. Selby district has a population of around 84,000 based on 2011 Census information.
1.1.2. The previous Selby Town Traffic model was developed by Mouchel with a base year of 2016. The model study area was around Selby town centre, extending to Cawood to the northwest of the town and Hemingbrough to the southeast. The model was used to test the transport impacts of potential development sites and infrastructure improvements included in the local plan.
1.1.3. WSP were commissioned by North Yorkshire County Council (NYCC) and SDC to develop the updated Selby District Strategic Transport Model (SDSTM) for a 2019 base year. This modelling suite will include a SATURN highway assignment model in addition to a variable demand model (VDM) being developed in CUBE Voyager.
1.1.4. It was agreed with NYCC and SDC that the project methodology will be developed incrementally and to undertake the work in two stages, namely;

- Stage 1- Identify network congestion hotspots

Stage 1 makes use of the currently available Selby Town Strategic model to identify congestion hotpots which could influence the development sites included in the Local Plan.

- Stage 2- Detailed model build

Stage 2 will focus on developing the detailed SATURN model for the areas identified in Stage 1 above to produce a representative robust modelling tool to support and test the proposed Selby District Local Plan.
1.1.5. WSP have completed work outlined in Stage 1 and shared the reports with NYCC and SDC for review, comments, and approval in August 2020.
1.1.6. In the discussion, following submission of the Stage 1 report, it has broadly been accepted that a district wide model update is required to ascertain the strategic highway network impacts of the developments identified within the log.

### 1.2 NEED FOR ADDITIONAL DATA

1.2.1. The aforementioned Selby Town Traffic Model focuses mainly on Selby Town area, whereas the Selby District Local Plan covers the entire district, implying that additional modelling and hence the need for additional data will be required.
1.2.2. It is stated in TAG Unit M1.1 that "data collection is necessary in order to inform the parameters that represent the model responses (calibration) and to provide a source of information against which the model can be compared to assure its quality (validation)."
1.2.3. To develop the updated transport model to a robust level compliant with TAG, a variety of data types were required either through existing sources or the commission of new Junction turning count surveys (MCC) and Automatic traffic counts (ATC).
1.2.4. This range and scope of data collection was necessitated by several primary purposes including:

- Development of demand matrices by mode (highway);
- Calibration of the highway assignment model through matrix estimation;
- Calibration and validation of the highway assignment model against respective TAG criteria; and
- Validation of journey time routes in the highway assignment model.
1.2.5. Analysis was undertaken of the quality and scope of existing data and then followed by a gap analysis to identify where existing data was insufficient in order to arrange surveys to infill this need.
1.2.6. Other datasets were also required to support this process including network development and assignment parameters.

### 1.3 PURPOSE OF THIS REPORT

1.3.1. This Transport Data Collection Report (TDCR) has been prepared to document the data collected for development of the updated SDSTM with reference to DfT's Transport Analysis Guidance (TAG) which defines the best practice for transport modelling, with particular reference to Unit M1.2 Data Sources and Surveys.
1.3.2. The content of this report is structured as follows:

- Chapter 2 - travel demand data;
- Chapter 3 - traffic count data;
- Chapter 4 - journey time data;
- Chapter 5 - additional data sources; and
- Chapter 6 - summary and conclusions.
1.3.3. It forms part of the reporting package for the SDSTM development that will include the highway Local Model Validation Report (LMVR) which documents how the data sources described in this report have been applied during the model development process.

## 2 TRAVEL DEMAND DATA

### 2.1 INTRODUCTION

2.1.1. Building a transport model necessitates the development of base year travel demand matrices for assignment. This construction required an understanding of the trip-making behaviour for Selby district including trip rates, trip length distributions and travel purpose.
2.1.2. This chapter details the specification and initial verification of the new mobile network data.

### 2.2 REVIEW OF EXISTING DATA

2.2.1. Due to the requirement for a district-wide model (see 1.2.1), the previous Selby model requires updating to meet this criterion and therefore it was necessary to obtain new travel demand data.

### 2.3 NEW DATA COLLECTION

2.3.1. Acquiring high quality origin-destination data is difficult. There are various sources identified within TAG however there is no definitive statement on their quality and acceptability for application in models; rather there is information on the advantages, limitations, and biases of these datasets.
2.3.2. Using mobile network data (MND) has the advantages of being captured for a wide area over a suitable period of time - in this case four weeks - therefore it is able to capture the trip making variability across a region which traditional sources such as roadside interview surveys (RSIs) do not. However, it is noted that RSIs will give explicit details for the data they do capture whereas MND relies on spatial analysis and tested algorithms to derive them.

## Mobile Network Data

2.3.3. The suitability of different demand data sources was considered as part of the model development scoping exercise and documented in the MSR. It was determined that MND would be used as the primary demand data source.
2.3.4. Telefónica were commissioned to derive mobile phone origin-destination (MPOD) matrices from MND supplied by O2. The data collection period covered all weekdays from 01/10/2019 to 31/10/2019, excluding the dates between 28/10/2019 and 31/10/2019 due to school holidays.
2.3.5. The data specification includes a Study area, and an Outer area. The study area boundary is shown in Figure 2-1. All trips that interact with the study area are included in the outturn MND matrices.
2.3.6. The mobile phone raw events available for this project were available for all zones within the Study area. Only the trips relating to the Study area, i.e., trips from, to and traversing the area are included in the matrix. Therefore, trips for external zones within or overlapping the Study area are only included if they interact with the Study area.
2.3.7. The data was provided in an agreed zone system, referred to as the MND Request Zone system, to make clear the distinction between these zones and the actual assignment model zone system. The MND Request Zone system is less detailed than the assignment zone system since O2 were confident in the spatial accuracy of the MND from LSOA upwards. It comprised 300 zones of which 205 were within the study area. The Request Zone system is illustrated in Figure 2-1.
2.3.8. Details on MND verification is detailed in the highway Local Model Validation Report (LMVR) as well as the Telefónica OD Demand Data Report attached in Appendix A. These documents report on the detailed MND data specification, analysis, and verification.

Figure 2-1 - MND Study Area

### 2.4 DATA VERIFICATION AND CLEANSING

## Mobile Network Data

2.4.1. Details on MND verification is detailed in the highway Local Model Validation Report (LMVR) as well as the Telefónica OD Demand Data Report attached in Appendix A. These documents report on the detailed MND data specification, analysis, and verification.
2.4.2. The key conclusions from that report are summarised as follows:

- All the zones within and outside the study area have trips.
- For motorised trips (excluding HGV), the majority of trips in the matrix are the Internal from/to external trips (48\%). Long distance trips between the external regions represent a significant $39 \%$ whilst the intra-study area trips make up a small proportion (around 14\%), of the travel demand from Selby district.
- As regard HGV, the majority of trips in the matrix are the external (around 63\%). Intra-study area trips make up around $33 \%$.
- The comparison with TEMPRO total trips showed that the MND matrix is significantly underrepresenting the total amount of trips in the study area.

Table 2-1 - MND Verifications: Average Weekday Total Two-Way Trips - All Modes

| District | All Modes |  |  |
| :--- | :---: | ---: | :---: |
|  | MND | TEMPRO | $\bar{\circ}$ ō Diff. |
| Selby District | 171,993 | 287,785 | 0.60 |

- The TLD analysis showed that a consistent part of this gap is produced by a shortfall in short distance trips for all purposes combined. These gaps will be infilled using the synthetic matrix.

Figure 2-2 - MND Verifications: TLD Comparison - All purposes and all modes

- The purpose split between 'Work' and 'Other' in the MND dataset closely reflected the purpose split in TEMPRO when education and work where defined together in TEMPRO. The matrix build will initially assume that the 'Work' category also contains education trips.

Table 2-2 - MND Verifications: Work/Other Split Proportions

| Purpose | MND | TEMPRO |
| :--- | :---: | :---: |
| Work (HB and NHB) | 0.33 | 0.38 |
| Other (HB and NHB) | 0.67 | 0.62 |

- In the MND the category Other includes "employer business" and 'Other' trips. A method will be required to segment the MND into commute, business, and other user classes.
- Other non-car highway trips -LGVs and bus - will need to be subtracted from the motorised component.
- The analysis of the HGV matrix showed that the MND matrix is underrepresenting the HGV trips in the study area. Therefore, additional data will be required to fill these gaps in the matrix.

## $3 \quad$ TRAFFIC COUNT DATA

### 3.1 INTRODUCTION

3.1.1. Traffic count data was required for the calibration and validation of the highway model against the criteria set out in TAG Unit M3.1 including:

- Calibration of the trip matrices through matrix estimation;
- Verification of the trip matrix across screenlines; and
- Verification of individual link flows.
3.1.2. This requires a substantial amount of quality data in order to cover the model study area in sufficient detail. This includes both:
- Automatic traffic counts (ATCs): permanent or temporary (typically a two-week period) surveys at a link level which give more reliable estimates for traffic volumes accounting for some day-to-day variability; and
- Manually classified counts (MCC): single day surveys undertaken for twelve hours which provide a more reliable vehicle classification plus data encoded on specific turning movements.
3.1.3. This chapter describes the review of existing data, the surveys commissioned, and the traffic data verification and cleansing processing undertaken.

### 3.2 REVIEW OF EXISTING DATA

3.2.1. Prior to considering new count surveys, an exercise was undertaken to establish availability of existing count data within the areas of interest. Existing counts were identified through two pathways. The first was knowledge of common data sources consisting of:

- The Traffic Flow Data System (TRADS) which is a collection of permanent ATCs on the strategic road network (SRN) which record traffic volumes at 15-minute intervals with classification determined by axle length. These are maintained by Highways England and available through their online database WebTRIS; and
- The DfT Count Database which is a collection of traffic counts undertaken on behalf of the DfT for single days on an annual basis at various locations on the major (motorways and A roads) and minor road network which is also available online.
3.2.2. The second pathway involved identification of counts which had been used for previous and ongoing studies including:
- A comprehensive set of ATC (including ATC at RSI sites) and MCC surveys commissioned 2016 as part of the model build by Mouchel;
- Historic count data in the study area provided by NYCC and SDC, as well as contacting additional traffic survey companies; and
- C2 permanent count site dataset hosted by North Yorkshire County Council providing data for parts of the study area.
- MCC surveys in Church Fenton and Tadcaster.
3.2.3. The existing ATC and MCC survey locations are mapped in Figure 3-1. Table 3-1 summarises the existing sources in more detail.

Figure 3-1 - Existing ATC and MCC data locations

Table 3-1 - Existing Sources of Traffic Count Data

| Source | Count Type | Survey Period | Data Type |
| :--- | :--- | :--- | :--- |
| 2016 Model Build | Automatic Traffic <br> Count | Generally two-week periods <br> in various years and | Data available in intervals of <br> between fifteen mins and |
|  | Twelve-hour periods for <br> single days in various years | Counts have been classified <br> into five vehicle classes |  |
| TRADS (Highways <br> England) | Permanent automatic <br> count sites on the SRN | Permanent | Data is not fully classified |
| DrT Counts - Major <br> Roads | Classified counts | Single day counts | Data is generally for <br> classification purposes to <br> support an existing ATC |
| DrT Counts - Minor <br> Roads | Classified counts | Single day counts | Data is generally for <br> classification purposes to <br> support an existing ATC |
| NYCC/SDC - <br> historic data | Temporary Automatic <br> Traffic Count | Generally two-week periods <br> in various years and <br> months | Data available in intervals of <br> between fifteen mins and <br> one hour |
|  | Manual Classified <br> Count | Twelve-hour periods for <br> single days in various years <br> and months | Counts have been classified <br> into five vehicle classes <br> (Car/Taxi, LGV, OGV1, <br> OGV2 and PSVs) |
| North Yorkshire <br> County Council - <br> C2 | Permanent automatic <br> count sites in North <br> Yorkshire | Permanent | Pata is not fully classified |
| Other Counts - <br> historic data | Manual Classified <br> Count | Twelve-hour periods for <br> single days in various years <br> and months | Counts have been classified <br> into five vehicle classes <br> (Car/Taxi, LGV, OGV1, <br> OGV2 and PSVs) |

### 3.3 NEW DATA COLLECTION

3.3.1. A gap analysis was undertaken to establish traffic significant links and junctions within the study area which were not covered by the existing data or where deficiencies or limitations had been identified in the existing data such as survey month or consistency with other counts. As a result of this exercise, a large data collection commission was undertaken.

## Automatic Traffic Counts (ATC)

3.3.2. There were 54 ATC surveys undertaken over a 3 -week period for October 2020, concluding before the start of the half-term holiday ( $28^{\text {th }}$ October 2020). The data obtained was tabulated by survey day with traffic volume reported in fifteen-minute intervals.
3.3.3. The locations were chosen based on proposed screenlines and cordons, watertight coverage of the district boundary and any other key links not covered by those criteria or existing data. The locations are shown in Figure 3-2 (red pins).

## い (1)

## Manually Classified Counts (MCC)

3.3.4. There were 59 MCC surveys undertaken for a twelve-hour period (07:00-19:00) for one day in October 2020. The data was tabulated in fifteen-minute intervals with flow volumes reported by at least six vehicle types:

- Pedal cycle / motorcycle;
- Car;
- Light Goods Vehicle (LGV);
- Other Goods Vehicle Type 1 (OGV1);
- Other Goods Vehicle Type 2 (OGV2); and
- Bus and Coach.
3.3.5. The locations corresponded to an ATC survey and the sample was chosen to provide local classified data for Selby and the key towns across the district to supplementing existing data. The locations are shown in Figure 3-2 (blue pins).

Figure 3-2 - Location of ATC and MCC Surveys (red = ATC; blue = MCC)

### 3.4 DATA VERIFICATION AND CLEANSING

3.4.1. Due to the quantity and varying formats of count data collected, a structured approach to verifying and cleansing the data was essential to assure consistency of processing across the whole dataset. The steps undertaken are summarised as follows.

## Removal of Outliers

3.4.2. Outliers can occur through mechanical fault including equipment failure or tampering but also in the event of traffic incidents which restrict or divert drivers and such that the resultant values are out of line with the typical daily flows recorded during the rest of the data capture period. Commentary of any known incidents or roadworks during the survey periods was provided by Streetwise to assist with identification or explanation for such occurrences.
3.4.3. WebTAG Unit M1.2 recommends that all values outside a range of two standard deviations from the mean are considered as outliers and this calculation was undertaken for all ATCs by hour (MonThu).

## Count Factoring

3.4.4. As a large amount of data available was not undertaken in the base year October 2019, a set of seasonal factors based on C2 data were applied to reach a typical average October 2019 weekday. Due to the impact of COVID-19, 2020 count data was factored using all available 2019 and 2020 counts that were located on the same links. This data was then used to derive uplift factors by vehicle type.

## Directionality Checks

3.4.5. Consideration of directionality - or tidality - was undertaken as a sense check on all of the counts where possible. Tidal patterns in Selby are not as definitive as in a major city where access to/from the city centre would carry a higher inbound flow in the AM peak and a higher outbound flow in the PM peak to account for commuter and business trip patterns. This is due to gravitational pull towards Selby being counter-balanced by the gravitational pull towards York and Leeds. However, where patterns exist, they were applied as checks to the count data.
3.4.6. For example, consider ATC Site 3 A63 to the west of Selby, towards Leeds. It would be expected that the eastbound direction will primarily include trips inbound towards the Selby whereas the westbound direction will primarily include trips outbound from Selby. Due to the traffic to/from Leeds in addition to Selby traffic, it is expected that there would be pronounced peaks in both the AM and PM for both directions. The graphs in Figure 3-4 demonstrates that the observed daily flow at this location is consistent with the expected travel behaviour which provides a level of assurance in the quality of the data and verifies the manual aspect of the processing such as data labelling.

Figure 3-3 - Example of Directionality: ATC Site 3 Location

Source: Reproduced from Site 45 Survey Data

Figure 3-4 - Example of Directionality: ATC Site 3 Weekday Average Traffic

Source: Reproduced from Site 3 Survey Data

## Consistency Checks - Multiple Counts

3.4.7. Due to using data from various commissions, there were some locations which had multiple counts covering identical movements or links. A selective approach was used to determine which count should be retained in such cases which was based on various factors including:

- Age of the data with preference for most recent where applicable;
- Year of survey with preference for those which more accurately represent 2019 traffic flows (considering that traffic flows in 2020 were greatly reduced due to COVID -19 lockdowns);
- Month of survey with preference for more neutral months;
- Consistency checks between the counts to establish concurrence or scale of differences; and
- Consistency checks with nearby counts on the same link, where available, as a verification on which is more reliable if differences were established.
3.4.8. This principal extended to some cases with counts from different data sources on adjacent links in the model which had a significant change in volume, but there was no explanation for the magnitude of change. This inconsistency would impact on the calibration and validation if both counts were retained since achieving criteria for one count may exclude the other from achieving the criteria and vice versa. Similar checks were undertaken to review the data quality and consistency to order to determine which count should be retained in those cases.

## Classification

3.4.9. As stated in Section 3.3, some ATCs were commissioned with a corresponding MCC on the same link. ATCs were classified into cars, LGVs and HGVs using a global splitting factor from all available MCCs. This approach was also applied to C2 and WebTRIS count classification, using the DfT counts as the source for the splitting factors. It must be noted that separate splitting factors were calculated based on survey year and road type (Motorway, A roads and other roads).

## External Area

3.4.10. The existing traffic count data sources available to this study, referenced above, extended to cover parts of Knottingley and near York which are not in the study area. Data was not processed for external areas that would not be part of the model calibration and validation.

## Outturn Count Database

3.4.11. The outturn processed traffic count database is attached in Appendix B. This is the count dataset which is being used for highway model calibration and comprises 572 counts, post cleaning, consistency checks and classification. A shapefile has also been produced with supplementary fields including data source. Figures 3-5 and 3-6 summarise the source of data and survey year of data in the outturn count database.

Figure 3-5 - Calibration Count Database: Source of Data

Figure 3-6 - Calibration Count Database: Survey Year of Data

## 4 JOURNEY TIME DATA

### 4.1 INTRODUCTION

4.1.1. Journey time data was required for development of the highway assignment model, in line with guidance set out in TAG Unit M3.1, primarily for validation of journey time routes but also to inform the calibration of cruise speeds and to verify large junction delays which may occur in the model.
4.1.2. This section documents the review of existing journey time data and the surveys undertaken, the need for which was determined during the highway model calibration and validation.

### 4.2 REVIEW OF EXISTING DATA

4.2.1. Trafficmaster journey time data is a dataset owned by the DfT which is sourced via GPS (Global Positioning System) data from devices and trackers fitted to a variety of fleet vehicles (cars, LGVs and HGVs) and buses. The data is collected by the devices through identifying the location of each device every 1 to 10 seconds on ITN (Integrated Transport Network) links. It is acknowledged that the sample population for Trafficmaster can be skewed, including a bias within cars towards high end vehicles and with a higher than representative proportion of LGVs, however it can be considered as the most comprehensive big dataset readily available for journey times data.
4.2.2. Access to Trafficmaster data for this project was provided by NYCC, covering the North Yorkshire area. The data was processed internally and resulted in a summarised dataset listing link distance and average travel time for ITN links.
4.2.3. The data was extracted for thirty-six pre-defined routes, agreed with SDC, and which are illustrated in Figures 4-1 and 4-2. The outturn dataset is summarised in Table 4-1.
4.2.4. The data specification applied was weekday term time for all vehicle types in 2019 for three time periods:

- AM peak hour: 08:00-09:00;
- Inter peak period: 10:00-16:00; and
- PM peak hour: 17:00-18:00.

Figure 4-1 - Journey Time Data Collection Routes: Selby Urban Area

### 4.3 DATA VERIFICATION AND CLEANSING

## Trafficmaster data

4.3.1. The Trafficmaster data was verified and checked at a route level including:

- Cross-check of observed times against Google Maps;
- Average speed for the route, removing any links that were unreasonably over the speed limit or less than 5 kph ;
- Directionality and tidality between periods, particularly on radial routes; and
- Identifying specific locations with very large delays in the data.

## 5 ADDITIONAL DATA SOURCES

### 5.1 INTRODUCTION

In addition to the primary survey data discussed in previous chapters, there was a requirement to collect various other data sources to support the model build. This includes:

- Network data;
- Travel data; and
- Modelling parameters.

This chapter introduces each of these datasets and outlines their use within the SDSTM development.

### 5.2 NETWORK DATA

5.2.1. A large amount of GIS data is available through Ordnance Survey's (OS) OpenData program which can be used freely with copyright acknowledgement. The data obtained from OpenData included:

- Base mapping at various scales for reporting and presentation;
- Shapefiles for various geographical boundary definitions to define the zone system and other sectors and/or reporting areas which are used throughout the reporting.
5.2.2. Ariel and street view images from Google have provided a valuable source of information on the network to be modelled. Physical characteristics of the network, such as the number of lanes, lane markings and flare lengths have been ascertained based on this data source as well as bus lanes and HGV restrictions.
5.2.3. Traffic signal junctions within the model simulation area require operation data in order for them to be coded within SATURN. Traffic signal specifications were obtained from NYCC for the identified junctions which included data such as:
- Phase and stage diagrams;
- Phase minimum/maximum sets;
- Timetables defining minimum and maximum sets to apply by time period; and
- Phase intergreen times.
5.2.4. This data was provided by NYCC for signalised junctions across the network in a template format that was supplied by WSP. It included stage and phasing diagrams and, in most cases, observed green times that span multiple years. Where the year was not 2019, we believe that they are representative of 2019 timings
5.2.5. Where observed green time data was not available min/max times were used as the starting point. In a limited number of locations template coding was used to develop most likely timings.
5.2.6. Bus routing and timetable data was taken from the Routelines Dataset provided by Basemap for the year of 2019. Routelines is a dataset covering the whole of GB which contains a series of road links detailing the shortest journey taken by a bus between stops along a route. In addition, information on the route operator, number and name was recorded, as well as the service number and direction of travel. The dataset also contains service frequency information. All data is contained within a
shapefile for each route. The bus routes were joined to the highway network by matching each bus stop to the nearest highway node.

### 5.3 TRAVEL DATA

National Transport Model
5.3.1. The National Trip End Model (NTEM) is developed by the DfT to forecast the growth in trip origins and destinations up to 2051 as a standardised dataset across transport modelling. The forecasts are derived based on national projections of:

- Population;
- Employment;
- Housing;
- Car ownership (through NATCOP - National Car Ownership Model); and
- Trip rates.
5.3.2. Data from NTEM can be accessed through CTripEnd databases or TEMPRO (Trip End Model Presentation Program) which operates as a front end for NTEM. This has been used at various points in the modelling including:
- Verification of MPOD data;
- Data to support processing of MPOD matrices;
- Trip ends for development of synthetic matrices; and
- Trip end growth for model forecasting.

The latest version as of writing this report is 7.2, which was released in March 2017.

## National Travel Survey

5.3.3. NTS is an annual survey undertaken by the DfT containing travel diary information for journeys made from a sample of UK households. It provides a rich data source for understanding the trip making characteristics to be understood against background area type and socio-economic data for a range of variables including:

- Trip purposes;
- Mode share;
- Time of outward and return journeys;
- Trip time and trip length profiles; and
- Vehicle occupancies.
5.3.4. NTS data has been used at various points in the demand matrix development including:
- Verification of MND;
- Trip generalised cost distributions for calibration of synthetic matrices; and
- Trip return time factors for synthetic matrices to convert P/A to O-D.

## Census Journey to Work

5.3.5. Census Journey to Work (JTW) is a demand dataset from the 2011 census containing information on mode of travel to work between pairs of MSOAs. The data is encoded for MSOA of residence, MSOA of workplace and mode of travel to work by various categories. This is national dataset and provides an observed volume and distribution of trips between MSOA pairs. The limitations are noted that it only represents one trip purpose segment, and the data is eight years old compared to the Selby District model base year.
5.3.6. JTW data has been used at various points in the demand matrix development including:

- Verification of MND.

## Experian Mosaic Data

5.3.7. Additionally, Experian Mosaic data has been used. As Census Journey to Work (JTW) data was collected eight years prior to the model year and the pandemic placing more reliance on the synthetic matrix, it was decided to use the more up-to-date Experian Mosaic dataset to derive the splitting factors for population figures. The Mosaic dataset is postcode based which allowed for easy aggregation of the statistics to the model zone system and the data was cross checked against census data for validation purposes.

### 5.4 MODELLING PARAMETERS

## TAG Databook

5.4.1. The TAG Databook is released by the DfT and includes all of the modelling and appraisal values referenced within the various guidance documents. This provides various parameters for the assignment models in value (base) year (2019) and price year (2010) including:

- Values of time;
- Vehicle operating costs; and
- Vehicle occupancies.

The latest release is Nov 2021 which has been used for the base year modelling.

## 6 SUMMARY AND CONCLUSIONS

### 6.1 SUMMARY

6.1.1. This report presents a summary of data collected for the base model development of the updated Selby District Strategic Transport Model (SDSTM) focused on three primary areas of travel demand, traffic counts and journey times. Specifically, the report covers:
6.1.2. Data requirements and specification for the model;

- A review of existing data sources;
- Collection of new data;
- Verification and cleansing of content; and
- Review of additional data sources required.
6.1.3. For each dataset, the initial phase considered the specification of data to meet the technical requirements and assurance required of the model. For travel demand data the requirement for, and technical specification of mobile phone data were covered in detail as part of the project brief and Model Specification Report. The principals established in those prior stages followed through into the data collection and verification stage as reported herein.
6.1.4. For other data types, known sources were reviewed for their coverage and quality within the SDSTM modelled area to assess their suitability for use. In addition to existing data, traffic count surveys were undertaken in October 2020 which followed the analysis to identify gaps or issues with existing data. This represented a large, multi-modal, and comprehensive collection of new survey data.
6.1.5. Following collation of data, verification and cleansing was undertaken to ensure an adequate source of information. Despite the checks being unique to the data in question, similar principles were adopted for each approach which included as a minimum adherence to the specification, completeness, and logic and sense-type checks. Details of these processes are presented in this report with further findings and details to be presented in the respective highway Local Model Validation Report.
6.1.6. In particular, the stepwise approach to cleansing the traffic count data is presented in this report with reference to specific examples where appropriate. The outturn summary reports $\sim 47 \%$ of calibration counts were surveyed in 2018 or 2019. Demand data verification is presented in detail within the Mobile Network Verification appendix and forms a robust analysis for informing the requirements of the prior matrix development process. In particular, the reporting indicates a logical set out outcomes from the defined tests with limitations occurring through potential misallocation across variables rather than any fundamental issues with the dataset. In particular, it is concluded that the demand data is fit for purpose for the development of SDSTM.

### 6.2 CONCLUSIONS

6.2.1. The data collection process for the Selby District Strategic Transport Model development has made use of a diverse range of sources to ensure that network supply, travel demand and model calibration and validation data is appropriately specified for the development of a transport model satisfying all of the attendant requirements of accuracy to subsequently deliver traffic forecasts according to the current agreed model application.
6.2.2. This process followed a systematic approach for each data type. This includes specification of needs, review of quality and availability of existing data, commission of new data surveys and verification and cleansing of data content. The approach will ensure confidence in the model development.
6.2.3. Further data collection will continue in the project including the collation of forecast year information relating to infrastructure and development for which a similarly diligent approach will be adopted.

## Introduction \& Project Scope

## Introduction

Telefónica is a mobile network operator ( O 2 in the UK), providing telephony services to over 22 million UK customers in both the public and private sectors. To ensure this service, Telefónica operates a network which supplies continuous nationwide coverage to each customer phone (device). The network and phone are in frequent communication to provide service. Intimate understanding of these networks allows Telefónica to build a contextual understanding of the movement of devices in space and time in the real world, with each phone creating events at specific points in time and space. These are chained into 'breadcrumbs', demonstrating whether each phone is moving or stationary at any point in time.

The result of Telefónica's processing creates a vast and valuable dataset which describes the movement and flow of O2 users across the UK. We track devices anonymously and associate each device with attributes derived from the user's contract (age, gender, contract type and billing address) or their observed behaviour (affluence, lifestyle, home and work location and other points of interest). In aggregate, therefore, mobile phone data provides a robust insight into the movement patterns of the UK population.

Given the nature of mobile phone data, it can represent movements on a macro basis across larger areas effectively. The technology is generally better at identifying longer trips and those where the user dwells at their destination for a more extended period. For this reason, the data should not be used in isolation but combined with other data sources before application.

Customer privacy is of utmost importance to Telefónica. All events processed are by-products of the core telephony network, and the process does not affect any user's handset. We anonymise the records before storing them in the analysis platform, so all analysis of behaviour is done in a completely anonymous separate environment. We aggregate outputs from the analysis such that we do not provide any individual-level data to clients.

## Scope

WSP requested Telefónica to prepare origin-destination matrices for travel around Selby. We included trips if they penetrated a cordon, as shown in Figure 1.

Figure 1: Image showing the extent of the model cordon.
We allocated trips to a start and end zone based on a zone system agreed with WSP, featuring a total of 300 zones. WSP provided the zoning system disaggregated in the following way:

- Cordon area (205 zones)
- Outer zones (95 zones)

Figure 2 shows the full zoning system, including the cordon area.

Figure 2: Image showing the zones used to identify the start and end point of trips.

We segmented trips by different variables; the core segmentation variables are as follows:

- By travel mode:
- Total Motorised Road
- HGV
- By travel purpose:
- Outbound home-based work (OB_HBW)
- Inbound home-based work (IB_HBW)
- Outbound home-based other ( $\overline{\mathrm{OB}}$ _HBO)
- Inbound home-based other (IB_HBO)
- Non-home-based work (NHBW)
- Non-home-based other (NHBO)
- By the time of day period into:

| - | AM Peak Period | $(07: 00-10: 00)$ |
| :--- | :--- | :--- |
| $\circ$ | Interpeak Period | $(10: 00-16: 00)$ |
| $\circ$ | PM Peak Period | $(16: 00-19: 00)$ |

We segmented all trips into these brackets according to the time they entered the cordon.

## Study Period

We sampled trips in two separate periods, using weekdays (Monday to Friday) between $1^{\text {st }}$ October 2019 and $31^{\text {st }}$ October 2019. We have excluded the dates between the $28^{\text {th }}$ and the $31^{\text {st }}$ of October 2019 due to school holidays.

The final origin-destination matrices are therefore made-up of 19 days in October 2019.

## Mobile Phone Technology

## Overview of the Cellular Network

A cellular or mobile network is a wireless network distributed over land areas called cells; each served by at least one fixed-location transceiver which is known as a cell site or base station. In a cellular network, each cell uses a different set of frequencies from neighbouring cells to avoid interference and provide guaranteed bandwidth within each cell. When joined together, these cells provide radio coverage over a wide geographic area, enabling a large number of portable transceivers to communicate with each other and with fixed transceivers and telephones anywhere in the network, via base stations, even if some of the transceivers are moving through more than one cell during transmission.

Adjacent cells form groups of cells. The names of these groups depend on the generation of the cells. For simplicity in this document, we will use the 2G grouping, which is LAC. LACs overlap and vary in size, depending on the area. Grouping cells into LACs is essential for the collection of event data.

## Event Data

O2 mobiles phones generate "events" as they communicate with the national cell network. We link each event to a persistent yet anonymised user ID. Telefónica stores a timestamp as well as the cell ID of the cell that recorded the event. We can analyse the spatial and temporal distribution of events to determine users' movement patterns. We classify events as either active or passive. It is the combination of both of these types of events that allow Telefónica to build a representative, stable dataset. Without the inclusion of passive events, our sample would be biased toward more active users, and individual user profiles would be biased towards locations where they made calls.

## Active Events

Connection events occur when a user turns their phone on or off, loses or regains connection
Call events occur when a user makes or receives a phone call, or moves between cells when on a call

Text events occur when a user makes or receives a text message

## Passive Events

Movement events occur when a user moves from one LAC to another. LACs consist of nearby cells in the same band - so users also create passive events when they transition between $2 \mathrm{G} / 3 \mathrm{G} / 4 \mathrm{G}$ coverage. These events ensure that the analysis process will record journeys that cover more than one LAC. The collection of these events is vital for accurately observing trips and allocating them to the correct mode.

Time-based events occur whenever a user does not create an event for a sustained period of 3 hours. We use these events to identify longer dwells even if they are in the same LAC as the previous dwell.

## Methodology

## Process Overview

Figure 3 summarises the process used to create the OD matrix deliverables. We have described each step in more detail in this chapter.

Figure 3: Process diagram of the existing methodology.

## Collection of event data

As described in section two, mobile phones regularly generate events. These are collected ('probed') by Telefónica for network management and billing purposes. The events are stored in a database to enable an analysis of travel patterns. Telefónica has access to data relating to the whole of the UK for the last five years, but for this project, we analysed data for 30 specific weekdays. Although only these 30 days were used to create the OD matrix, we used the data from other days to define a number of the core segmentations (e.g. identifying valid users and home locations).

## Conversion of Event Data to Dwells and Journeys

Telefónica converts the raw event data into 'dwells' (or settles) and 'journeys'. We consider the geographic proximity of events, the propensity for phones to 'flicker' between cells without changing their location and the timing of each event. In general, we classify a dwell whenever a user is assumed to be stationary in one distinct place for at least 30 minutes. We classify the period between two dwells as a journey. We store the cells of the events and combine them to make up each dwell and each journey as 'via points', these can be interrogated to understand the route of each journey or the location of each dwell. We represent journeys as person trips and not vehicle trips.

Figure 4: Processing event data: dwells and journeys.

## Removal of invalid users

Events are created by all O 2 users, corresponding to about $30 \%$ of the UK population or circa 22 m connections. We allocate each user an anonymised user ID; this ensures that we cannot trace their records back to a particular person. We set up the anonymous ID to make sure that it is consistent even if a user changes their phone. If a user leaves O 2 however, their records will cease. We run a filtering process to identify and remove these inconsistent users.

Also at this stage, a filter is applied to ensure that we only include mobile devices; we exclude machine to machine (M2M) devices, tablets and GPS units, as they are less likely to be carried by users at all times. Large business contracts are also removed from the sample to reduce the risk of double-counting users who carry two phones.

## Generation of Points of Interest

We define Points of Interest (POI) where a user has multiple dwells which overlap each other. By analysing all of the dwells associated with a particular POI, the position of the POI can be identified with a higher degree of accuracy as we take the cell information from each of the dwells that contribute to the POI. We compare and analyse the relevant cell geographies associated with a POI and match them to the zone system agreed with WSP. We associate each POI with a specific zone. Every time a user visits a cell associated with one of their POls, we record this as a trip to the associated zone.

## The categorisation of Points of Interest

The categorisation of POls is based on the temporal patterns of a user's dwells at each POI throughout the study period. We classify a POI where a user spends a significant amount of time overnight as their home POI. All users must have a home POI. We classify POIs where users spend a substantial period during the working day as their work POI. We classify all other POls that are not 'home' or 'work' as 'other' POIs.

Figure 5: Example POI classification
The POI schematic used is designed to detect regular daytime commuters. As such, it may not correctly capture travel patterns for users who behave in unusual ways:

- Working from home: users who work from home will have a home POI, but no work POI.
- No fixed place of work: users who have an inconsistent place of work (e.g. plumbers) will not usually have a work POI unless they spend most of the study period working at the same site. We include their trips to work will often in the home-based-other matrix.
- Shift workers: users who work unusual hours, e.g. night shifts, will not usually have a work POI - we include their trips in the home-based-other matrix.
- Education trips: Users in education that travel to school from home will usually have a home POI and a work POI. Their travel patterns are very similar to regular commuters. Users in education that live on campus or travel a very short distance to school will likely only have a Home POI, as we are unable to differentiate their work/education location from their home location.

## Calculation of expansion factors

O2, Tesco Mobile, and Giffgaff combined market share constitute a representative sample of the UK population with over $32 \%$ of the UK mobile network provider market-share. This market share varies across the country, under-representing some age, gender and socioeconomic segments due to technology penetration (phone devices ownership) and over-representing others. When expanding mobile data to represent the entire population, we need to take these biases into account. The process for calculating the expansion is as follows:

- For every valid user (everyone with an ongoing contract with O 2 during the entire duration of the study period), identify their home POI. We exclude under 12 years old as we understand that they are very poorly represented in the data, and we expect them to be less independently mobile.
- Count the number of primary home POls in each MSOA (Middle Super Output Area).
- For each MSOA, compare the number of primary home POls with the mid-year ONS population estimates from 2017 (the most recent available) for the over 12 population, with a small adjustment for growth since then. We associate each MSOA with an expansion factor which is equivalent to the census population as described previously divided by the number of primary home POIs in that MSOA.
- For each region, compare the proportion of primary home POls for users in each age/gender/socioeconomic bracket with the proportion from the 2017 ONS population estimates. We associate each region with an age/gender/socioeconomic reweighting factor
which is equivalent to the proportion of the census population in that age/gender/socioeconomic bracket divided by the proportion of primary home POls of users in that age/gender/socioeconomic bracket.
- We attach the expansion factor and the age/gender/socioeconomic reweighting factor based on the user's primary home POI and the age/gender/socioeconomic information of that user.
- All trips made by each user, regardless of origin or destination, are scaled up according to the weight of the user.

## Categorising journeys by purpose

Journeys are assigned a travel purpose based on the categorisation of their start and end POI:

| Origin POI | Destination POI | Purpose |
| :---: | :---: | :---: |
| Home | Work | Outbound Home-Based Work (OB_HBW) |
| Work | Home | Inbound Home-Based Work (IB_HBW) |
| Home | Other/Home | Outbound Home-Based Other (OB_HBO) |
| Other | Home | Inbound Home-Based Other (IB_HBO) |
| Work | Other/Work | Non-Home-Based Work (NHBW) |
| Other | Work | Non-Home-Based Work (NHBW) |
| Other | Other | Non-Home-Based Other (NHBO) |

Table 1: Trip Purpose Categories

Education trips: Tertiary education trips made by users will usually be included in the home-based work trips because they are trips between home and a place where the user regularly spends long periods during the time. We recommend that the customer uses alternative datasets to split out and supplement education trips from the matrices.

Note that education escort trips, where observed, will usually be included in home-based-other trips.

## Identify journey mode

At this stage, we analyse the route and characteristics of each journey to allocate the journey to one of the following modes:

- Rail - we classify journeys which follow the rail network and which exhibit 'clustering' (see description below) as rail trips.
- Motorised Road - we take any remaining trips will be allocated to the road matrix - note that this includes coach, bus, and LGV trips as well as car trips.
- HGV - we have developed an algorithm to split HGV trips out from other motorised road modes. The algorithm considers, on a user basis, the number of long-distance trips and the average distance travelled in a week per user. We consider users who frequently travel long distances on the road, and we identify HGV drivers using a speed percentile calculation, with the assumption that HGV travel is consistently slower than other road traffic. For each user classified as an HGV driver, we consider all their non-home-based trips as HGV trips.
- Slow mode - as a final step in the mode detection methodology, we identify a percentage of trips in each of the shorter distance bands as "walking/cycling" trips. The methodology classifies the slowest trips (by travel speed) as "walking/cycling" trips. We do not expect to capture all walking/cycling trips in the mobile network data, as a large proportion of these types of trips in the lower distance bands will be too short. The journeys that we classify as

[^0]walking/cycling will only be a sub-set of walking/cycling journeys made; for this project, we have removed these journeys from the motorised road matrix.

Clustering: we distinguish between road and rail journeys by identifying cell pairs that show characteristic travel time patterns for either of the two modes. When a train crosses the boundary of a LAC, the phone of every O 2 customer on board will generate a passive event. These events will occur in quick succession (depending on the length and speed of the train, as well as the device type and the current state of the mobile network), which will result in clearly identifiable clustering patterns. We classify specific cell pairs as "rail" when these patterns become apparent. When we do not observe clustering, we classify them as a road pair. On the road, we usually observe a continuous flow of cars, and events (i.e., movements from one LAC to another) also occur continually. An algorithm examines the clustering patterns of all the journeys in the system to identify rail and road journeys.

Figure 6: Characteristic clustering pattern of a rail cell pair

Figure 7: The lack of any identifiable cluster indicates a road cell pair

## Select Trips that penetrate cordon

Once every journey is associated with a mode, we map it to a route based on the events (via points) generated during the journey. We compare these routes against the cordon agreed with WSP and only included those trips which penetrate this cordon in the matrix.

## Identify the time of the journey

We allocate journeys are to a time band based on their start time entering the cordon.

## Create OD matrix split by mode

Once we allocate all journeys a time, purpose and mode, it is straightforward to create the OD matrix outputs. We allocate trips to a time-period, mode and purpose and include them in the relevant part of the matrix.

Stochastic rounding: to preserve personal data, Telefónica does not provide outputs relating to the movement of individuals. In the context of an origin-destination matrix, we achieve this by creating an average result representing multiple days of observations, and by rounding results to integer values.

Applying standard rounding methods would cause errors in the outputs because they would cause many cells in the matrix to be rounded to zero, reducing the volume of trips in the data. To avoid this, we use stochastic rounding whereby the probability of rounding a value up or down depends on a fractional part - so a value of 0.1 has a $90 \%$ probability of being rounded down to zero and a 10\% probability of being rounded up to one. This method of rounding preserves the overall volumes of the matrix (and the size of any part of the matrix large enough for the rounding interval to be negligible) while also preventing the disclosure of individual-level data.

## Validation

Before releasing the data, Telefónica carries out a range of validation checks to ensure internal consistency and check against relevant alternative data sources. Checks are usually limited to zones which are within the cordon because we only include trips if they penetrate the model cordon.

## Comparison of Mobile Network Data (MND) home-based trip origins against Census zone home population

Figure 8 shows the number of outbound home-based trips starting in each zone within the cordon on an average day in the study period against that zone's home population, based on the 2017 mid-year Census (we extracted the population of each client zone from the Output Areas within each zone). The correlation between the census population and outbound home-based trips has an $R^{2}$ of 0.51 .

Figure 8: Outbound Home-Based vs Census Home Population in Urban areas

## Comparison of MND work-based trip destinations against Census zone workplace population

Figure 9 shows the number of outbound home-based work trips arriving at each zone within the cordon during a typical day in the study period against the work population of each zone (based on Census workplace statistics). The figure below includes part-time workers from Census workplace population and will include part-time workers where a work POI was identified as per the definition given in the methodology section in this document. We identified a strong correlation with an $\mathrm{R}^{2}$ of 0.97 .

Figure 9: Inbound work-based trip destinations vs Census Work Population

## Comparison of inbound trips and outbound trips per zone

Figure 10 shows a comparison of the number of trips starting (by all modes and purposes) with the number of trips ending in each zone. As expected, we see a very strong correlation, with an $R^{2}$ of 0.99 .

Figure 10: Trip Symmetry by Zones

## Comparison of the MND trip length distribution for all trips against NTS trip length distribution

Figure 11 shows a comparison of the trip length distribution for trips starting in the cordon (by all modes and purposes) with the trip length distribution reported in the National Travel Survey (NTS) for the Yorkshire and The Humber (NTS9911).

Figure 11: Trip Length Distribution (Mobile Network Data vs NTS)

At first glance, the match between the two datasets is poor, with the NTS containing more trips below five miles and the mobile data containing more trips above five miles. However, we find a better match when we compare trips above five miles in length (Figure 12):

Figure 12: Trip Length Distribution for trips greater than 5 miles.

This result indicates that trips above five miles in better represented in the mobile phone data, while trips below five miles in length are only partially represented in the mobile phone data. Short trip under-representation is a well-known limitation of mobile phone data as we can only represent trips if the device moves between cells, which in rural areas, can be large. We recommend that the customer uses secondary datasets to correct for this bias in the mobile phone data.

## Comparison of the MND trip length distribution of commutes against Census journey to work data

We compare the trip length distribution from the Mobile Network Data against the Census journey to work (JTW - WU03EW) data for road trips. The graph below represents the distance profile of all journeys captured in the matrix of over 5,000 metres.

For this chart, we are using the straight-line distance between MSOA pairs to calculate the journey distance of commutes. We are also only considering MSOA pairs (usual place of residence / usual place of work) in which there is a value in both the Mobile Network Data matrix and the Census Journey to Work matrix.

Figure 13: Trip Length Distribution for road-based commutes greater than 5 km (Mobile Network Data v Census)

In Figure 13 we can see that the trip length distribution for commutes greater than 8,000 metres show a significant alignment with Journey to Work Census.

## Comparison of trip rates based on expansion targets against the zonal tripends derived.

We calculate the trip rate for the period of study and compare it against the NTS9903 table for the equivalent transport modes as follows:

NTS trip rate: the sum of car drivers, van drivers, car passengers, van passengers, motorcycles, local bus users, other private transport users divided by 365 days in a year. Please note, this trip rate considers the entire UK population, not just the population of over-12s.

Telefónica matrix: the total weighted number of trips divided by the total weighted number of users captured in the matrix with a home located inside the study cordon.

NTS resulted in a trip rate of 2.75 against the Telefónica trip rate of 1.16. Several factors contribute to these differences:

- The lack of short-trips observed in the mobile network data. In the Yorkshire and The Humber region of England, approximately 40\% of all trips made are shorter than 2 miles.
- We are only considering trips made by users with a home located inside the cordon that start/end or pass through the cordon area, not all trips a user makes (i.e. trips that don't interact with the cordon). The relative size of the area studied will have an impact on this metric as many journeys (external to external, not crossing the cordon) will not be captured.

## HGV trips against WebTRIS Annual Daily Flow

Figure 14 shows a comparison between MND and WebTRIS hourly flow data and MND trips assigned as HGV on the 24 of October 2019 from a node of the M62. A selection of our internal routing nodes are compared with the closest WebTRIS count points (see figure 15 for locations) on the same road and in the same direction.

Figure 14: Comparison of HGV trips between MND and WebTRIS data for 1st November 2018

Figure 155: Location of MND routing node and WebTRIS count point

## Summary

The data for this project has been collected on a 19 -day sample using established and proven methodologies for the application of mobile phone data to transport modelling. We have shown through validations that the mobile data provided is internally consistent and compares well to the secondary datasets. We performed checks that are limited to publicly available datasets and are not intended to be exhaustive. We, therefore, advise further comparisons with appropriate local datasets before applying the matrices to a transport model.

We have highlighted a few biases in the methodology and validation sections, all of which are recognised limitations of mobile phone data. The core limitations are as follows:

- We are only representing trips made by those over 12 years old.
- Comparisons with trip length distributions from NTS indicate that trips below 5 miles are likely to be under-represented in the mobile phone data. However, this will depend on the cell resolution - in urban areas short distance trips are more likely to be represented, while in rural areas the threshold may be slightly higher.

We recommended that the customer uses secondary data sources to enhance the mobile phone data to correct for them.
